Timed delivery

How fast can we deliver without losing the cargo?

A fast and reliable run

Cross 60 cm with the cube aboard

Stay in lane and stop in the clear runout

Time three trials. Keep failed attempts.

GREEN steady: on **ORANGE flashing: charge** **RED flashing: stop + mentor**

Center button lights. A letter on the display is your program’s output.

One run with a speed input

```
speed = 200
await signal("R")
await pause(1000)
await sprint(speed)
await signal("D")
```

Our prediction

What might change if speed becomes 300?

What must stay the same for a fair comparison?

Recipe fragment: load the complete supplied project

Robot trials and cradle builds

Driver edits and starts after “clear.”

Navigator predicts and resets the stopped robot.

Observer records time and delivery success.

Build team makes and hand-tests a cargo cradle.

Rotate every 4 minutes; every 2 minutes in retests.

Times and successful deliveries

A: mentor tray at 200 — three runs

B: same tray, approved faster speed — optional

C: our cradle at the same chosen speed — three runs

Count successes first. Compare times for 3/3 valid sets.

Our evidence for the showcase

What did you learn about speed or the code?

What did our cradle change do?

Which result supports our showcase choice?
